<tr>
<th><strong>GLOSSARY</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Adaptive immunotherapy</strong></td>
<td>The transfer of immune cells for therapeutic benefit.</td>
</tr>
<tr>
<td><strong>ADCC, antibody-dependent cellular cytotoxicity</strong></td>
<td>A cytotoxic reaction in which the Fc receptor-bearing killer cells recognize target cells via specific antibodies.</td>
</tr>
<tr>
<td><strong>Adhesion molecules</strong></td>
<td>Cell surface molecules involved in cell–cell interaction or the binding of cells to extracellular matrix, where the principal function is adhesion rather than cell activation, e.g. integrins and selectins.</td>
</tr>
<tr>
<td><strong>Adjuvant</strong></td>
<td>Any foreign material introduced with an antigen to enhance its immunogenecity, e.g. killed bacteria, (mycobacteria), emulsions (Freund’s adjuvant) or precipitates (alums).</td>
</tr>
<tr>
<td><strong>Alloantibody</strong></td>
<td>Antibody raised in one individual and directed against an antigen (primarily on cells) of another individual of the same species.</td>
</tr>
<tr>
<td><strong>Allogeneic</strong></td>
<td>See page 124.</td>
</tr>
<tr>
<td><strong>Allotypes</strong></td>
<td>The protein of an allele which may be detectable as an antigen by another member of the same species. Plasma proteins are an example of antigenically dissimilar variants.</td>
</tr>
<tr>
<td><strong>Alternative pathway</strong></td>
<td>The activation pathways of the complement system involving C3 and factors B, D, P, H and I, which interact in the vicinity of an activator surface to form an alternative pathway C3 convertase.</td>
</tr>
<tr>
<td><strong>Anaphylatoxins</strong></td>
<td>Complement peptides (C3a and C5a) which cause mast cell degranulation and smooth muscle contraction.</td>
</tr>
<tr>
<td><strong>Anchor residues</strong></td>
<td>Certain amino acid residues of antigenic peptides are required for interaction in the binding pocket of MHC molecules.</td>
</tr>
<tr>
<td><strong>Antigenic peptides</strong></td>
<td>Peptide fragments of proteins which bind to MHC molecules and induce T-cell activation.</td>
</tr>
<tr>
<td><strong>APCs (antigen-presenting cells)</strong></td>
<td>A variety of cell types which carry antigen in a form that can stimulate lymphocytes.</td>
</tr>
<tr>
<td><strong>Apoptosis</strong></td>
<td>Programmed cell death: a mode of cell death which occurs under physiological conditions and is controlled by the dying cell itself (‘cell suicide’).</td>
</tr>
<tr>
<td><strong>Autologous</strong></td>
<td>Originating from the same individual.</td>
</tr>
<tr>
<td><strong>β2-microglobulin</strong></td>
<td>A polypeptide which constitutes part of some membrane proteins including the class I MHC molecules.</td>
</tr>
<tr>
<td><strong>Bcl-2</strong></td>
<td>A molecule expressed transiently on activated B cells which have been rescued from apoptosis.</td>
</tr>
<tr>
<td><strong>CD markers (cluster of differentiation)</strong></td>
<td>Used as a prefix (and number). Cell surface molecules of lymphocytes and platelets that are distinguishable with monoclonal antibodies, and may be used to distinguish different cell populations.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Cell adhesion molecules (CAMs)</td>
<td>A group of proteins of the immunoglobulin supergene family involved in intercellular adhesion, including ICAM-1, ICAM-2, ICAM-3, VCAM-1, MAd CAM-1 and PECAM.</td>
</tr>
<tr>
<td>Class I/II restriction</td>
<td>The observation that immunologically active cells will only operate effectively when they share MHC haplotypes of either the class I or class II loci.</td>
</tr>
<tr>
<td>Class switching</td>
<td>The process by which B cells can express a new heavy chain isotype without altering the specificity of the antibody produced. This occurs by gene rearrangement.</td>
</tr>
<tr>
<td>Clonal selection</td>
<td>The fundamental basis of lymphocyte activation in which antigen selectively causes activation, division and differentiation only in those cells which express receptors with which it can combine.</td>
</tr>
<tr>
<td>Collectins</td>
<td>A group of large polymeric proteins including conglutinin and mannose-binding lectin (MBL) that can opsonize microbial pathogens.</td>
</tr>
<tr>
<td>Colony-stimulating factors (CSFs)</td>
<td>A group of cytokines which control the differentiation of haemopoietic stem cells.</td>
</tr>
<tr>
<td>Constant regions</td>
<td>The relatively invariant parts of the immunoglobulin heavy and light chains, and the α, β, γ and δ chains of the T-cell receptor.</td>
</tr>
<tr>
<td>Co-stimulation</td>
<td>The signals required for the activation of lymphocytes in addition to the antigen-specific signal delivered via their antigen receptors. CD28 is an important costimulating molecule for T cells and CD40 for B cells.</td>
</tr>
<tr>
<td>Defensins</td>
<td>A group of small antibacterial proteins produced by neutrophils.</td>
</tr>
<tr>
<td>Dendritic cells</td>
<td>Derived from either the lymphoid or mononuclear phagocyte lineages. A set of cells present in tissues, which capture antigen and migrate to lymph nodes and spleen, where they are particularly active in presenting the processed antigen to T cells.</td>
</tr>
<tr>
<td>Domain</td>
<td>Segments or loops on heavy and light chains formed by intrachain disulphide bonds. Each immunoglobulin domain consists of about 110 amino acids.</td>
</tr>
<tr>
<td>Epitope</td>
<td>Part of an antigen that binds to an antibody-combining site or a specific T-cell surface receptor, and determines specificity. Usually about 9–20 amino acids in size.</td>
</tr>
<tr>
<td>Fas ligand</td>
<td>The ligand that binds to the cell surface molecule Fas (CD95) which is normally found on the surface of lymphocytes. When Fas ligand binds to its receptor, cell death (apoptosis) is triggered.</td>
</tr>
<tr>
<td>Genetic restriction</td>
<td>Describes the phenomenon where lymphocytes and antigen-presenting cells interact more effectively when they share particular MHC haplotypes.</td>
</tr>
<tr>
<td>Gut-associated lymphoid tissue (GALT)</td>
<td>Accumulations of lymphoid tissue associated with the gastrointestinal tract.</td>
</tr>
</tbody>
</table>
**Haplotype**
A set of genetic determinants coded by closely linked genes on a single chromosome.

**Hapten**
A substance of low molecular weight which is not itself immunogenic, but which can bind to an antibody molecule and produce a new antigenic determinant.

**Helper (T<sub>H</sub> cells)**
A functional subclass of T cells which can help generate cytotoxic T cells and cooperate with B cells in the production of antibody responses. Helper cells recognize antigen in association with class II molecules.

**Heterologous**
Originating from a different individual or different inbred line.

**Heterophile antigen**
Antigen which occurs in tissues of many different species and is therefore highly crossreactive, e.g. Paul–Bunnell antigen which reacts with both sheep and beef erythrocytes.

**HLA**
See page 36.

**Idiotype**
Unique antigenic determinant on the antigen-binding region of an immunoglobulin molecule.

**Hypervariable regions**
Amino acid sequences within the variable regions of heavy and light immunoglobulin chains and of the T-cell receptor which show the most variability and contribute most to the antigen-binding site.

**Immunoglobulin subclass**
Immunoglobulin of the same class that is detectable in the constant heavy chain region, and differs in electrophoretic mobility and antigenic determinant, and function, e.g. IgG1, IgG2, IgG3 and IgG4.

**Immunoglobulin supergene family (IgSF)**
Molecules which have domains homologous to those seen in immunoglobulins, including MHC class I and II molecules, the T-cell receptor, CD2, CD3, CD4, CD8 ICAMs, VCAM and some of the Fc receptors.

**Intercellular adhesion molecules**
Cell surface molecules found on a variety of leucocytes and non-haematogenous cells which interact with leucocyte functional antigen (LFA-1); e.g. ICAM-1 (CD54), ICAM-2 (CD102) and ICAM-3 (CD50).

**Integrins**
One of the ‘families’ of adhesion molecules, some of which interact with cell adhesion molecules, and others with components of the extracellular matrix.

**Isologous**
Originating from the same individual or member of the same inbred strain.

**Isotype**
The class or subclass of an immunoglobulin common to all members of that species. Each isotype is encoded by a separate immunoglobulin constant region gene sequence that is carried by all members of a species.

**Killer (K) cells**
Type of cytotoxic lymphocyte that is able to mediate antibody-dependent cellular cytotoxicity (ADCC).

**Langerhans' cells**
Antigen-presenting cells of the skin which emigrate to local lymph nodes to become dendritic cells; they are very active in presenting antigen to T cells.
**Lectin pathway**
A pathway of complement activation, initiated by mannose-binding lectin (MBL) which intersects the classical pathway.

**Leucocyte functional antigens (LFAs)**
A group of three molecules (LFA-1 (CD11a/CD18), LFA-2 (CD2) and LFA-3 (CD58)), which mediate intercellular adhesion between leucocytes and other cells in an antigen non-specific fashion.

**Linkage disequilibrium**
The association of two linked alleles more frequently than would be expected by chance.

**Memory cells**
Long-lived lymphocytes which have already been primed with antigen but have not yet undergone terminal differentiation into effector cells. They react more readily than naïve lymphocytes when restimulated with the same antigen.

**Mixed lymphocyte reaction (MLR)**
Proliferative response when lymphocytes from two genetically different (i.e. allogeneic) persons are mixed in cell culture. A vital test in matching donor and recipient prior to bone marrow transplantation.

**Mucosa-associated lymphoid tissue (MALT)**
Lymphoid tissue associated with the bronchial tree, gastrointestinal tract and other mucosa.

**Natural killer (NK) cell**
Type of cytotoxic lymphocyte that has the intrinsic ability to recognize and destroy virally infected cells and some tumour cells. Specializes in killing cells that express little or no MHC molecule.

**NfkB**
A transcription factor which is widely used by different leucocyte populations to signal activation.

**Perforin**
A granule-associated molecule of cytotoxic cells, homologous to complement C9. It can form pores on the membrane of a target cell.

**Reactive oxygen/nitrogen intermediates (ROIs/RNIs)**
Bactericidal metabolites produced by phagocytic cells, including hydrogen peroxide, hypophalites and nitric acid.

**Selectins**
Three adhesion molecules, P-selectin (CD62P), E-selectin (CD62E), and L-selectin (CD62L) involved in slowing leucocytes during their transit through venules.

**Superantigens**
Antigens (often bacterial, e.g. staphylococcal enterotoxins) which bind to the MHC outside the peptide-binding groove and stimulate all or most of the T cells bearing particular T-cell receptor V regions. Antigens must normally be processed in order to trigger the T-cell receptor. Superantigens are not processed but bind directly to class II and Vβ.

**Suppressor (TS) cell**
Functionally defined populations of T cells which reduce the immune responses of other T cells or B cells, or switch the response into a different pathway to that under investigation.

**Syngeneic**
Genetically identical or closely related, so as to allow tissue transplant.
TAP transporters A group of molecules which transport proteins and peptides between intracellular compartments.

T-cell receptor (TCR) The T-cell antigen receptor consists of either an αβ dimer (TCR-2) or a γδ dimer (TCR-1) associated with the CD3 molecular complex.

T-dependent antigens Require recognition by both T and B cells to produce an immune response.

T-independent antigens Can directly stimulate B cells to produce specific antibody.

Titre The highest dilution of a given substance, e.g. antibody, that will still produce a reaction with another substance, e.g. antigen.

Toll receptors A group of evolutionarily ancient cell surface molecules, e.g. the IL-1 receptor, some of which are involved in transducing signals for inflammation.

Transforming growth factors (TGFs) A group of cytokines, identified by their ability to promote fibroblast growth, that are also immunosuppressive.

Tumour necrosis factor (TNF) See page 101.

THE IMMUNE RESPONSE SYSTEM

INNATE (NON-SPECIFIC) AND ADAPTIVE (ACQUIRED) IMMUNITY

(Fig 3.1 and Table 3.1)

The innate component functions as a first line of defence and involves antigen-independent mechanisms. The adaptive component results from antigen-dependent activation, proliferation and differentiation (clonal expansion) of lymphocytes. It takes longer to mobilize but confers specificity and exhibits memory. The two are functionally interrelated in several critical ways, e.g. through cytokines and complement components.

CELLS AND MOLECULES INVOLVED IN THE IMMUNE RESPONSE

1. **Antigen-recognition lymphoid cells** (B and T lymphocytes)

**B lymphocytes** (see also Immunoglobulins, p. 105).

*Functions:* Humoral immunity – antibody production; control of pyogenic bacteria; prevention of blood-borne infections; neutralization of toxins.

*% of total lymphocytes:* 12%; mainly fixed.

*Site of production:* Produced in germinal centre of lymph nodes and spleen.

*Assessment of function:* Serum specific immunoglobulin levels; specific antibodies; immunoglobulin response to pokeweed mitogen; endotoxin and EBV.

**T lymphocytes**

*Functions:* Cell-mediated immunity; protection against intracellular organisms, protozoa and fungi; graft rejection; control of neoplasms.

*% of total lymphocytes:* 70–80%; mainly circulating; long-lived memory cells.

*Site of production:* Produced in paracortical region of lymph nodes and spleen.
Assessment of function: Delayed hypersensitivity skin reactions using candida, mumps and purified protein derivative (PPD); active sensitization with dinitrochlorobenzene (DNCP); lymphocyte transformation: mitogenic response to phytohaemagglutinin (PHA) and concanavalin-A; mixed lymphocyte reaction (MLR); lymphokine release.

Identified by: T-cell surface phenotypes identified by reaction with monoclonal Abs (Table 3.2 and Fig. 3.2).

T cells express either γδ or αβ T-cell receptors. αβ T cells are divided into CD4 and CD8 subsets. T cells are further subdivided into T_{H1} and T_{H2} on the basis of their cytokine profiles (Fig. 3.3).

Fig. 3.3 T-cell subsets.
T-cell subpopulations

Regulatory and effector T cells

Regulatory cells:
1. **TH helper T cells CD4⁺**: recognize antigen by means of the T-cell receptors in association with macrophage receptors. Produces cytokines and helps generate cytotoxic T cells and cooperates with B cells in production of antibody responses. Recognizes antigen in association with class II MHC molecules on the surface of antigen-presenting cells.
2. **TS suppressor T cells**: interfere with the development of an immune response of other T cells or B cells, either directly or via suppressor factors.

Effector cells:
3. **TC cytotoxic T cells CD8⁺**: regulate the immune response and can lyse target cells, e.g. viral or tumour antigens expressing antigen peptides presented by MHC class I molecules on the surface of all nucleated cells. Interleukin-2 (IL-2) is responsible for the generation of cytotoxic T cells.
4. **TDH delayed hypersensitivity T cells**: release mediators that cause an inflammatory response attracting macrophages, neutrophils and other lymphocytes to the site.

Other selected important CD markers

CD28: Present in highest amounts in activated T cells. It is a T-cell costimulatory molecule which plays a major role in T cell activation.

CD45RA: An isoform of CD45 associated with active T cells that respond poorly to recall antigen.

CD45RO: An isoform associated with memory T cells. Responds well to recall antigen.

CD95: Also known as Fas, binds Fas ligand and mediates apoptosis of activated T cells.

**T₉₁ and T₉₂ populations** (Fig. 3.4)
- CD4⁺ MHC class II-restricted T cells can also be subdivided into T₉₁ and T₉₂ populations based on their profiles of cytokine production.
- The T₉₁ profile is associated with production of IL-2, tumour necrosis factor (TNF)-β and interferon (IFN)-γ and is driven by IL-12.
- The T₉₂ profile is associated with IL-4, IL-5, IL-6 and IL-13 and is driven by IL-10.
- T₉₁ cytokines are involved in helping cell-mediated immunity and the T₉₂ cytokines mediate humoral immunity.
- T₉₁ cells can downregulate T₉₂ cells and vice versa.

**T-cell antigen receptor (TCR)** (Fig. 3.5)

TCR complex comprises a disulphide-linked heterodimeric glycoprotein that enables T cells to recognize a diverse array of antigens in association with MHC molecules. It consists of α and β subunits or occasionally γ and δ subunits. It is associated at the cell surface with a complex of polypeptides known collectively as CD3 which is required for activation of T cells.
- Consists of α, β subunits or, less commonly, γ or δ subunits.
- Differences in the variable regions of the TCR subunits account for the diversity of antigenic specificity among T cells.
- TCRs only recognize antigenic peptides bound to class I or class II MHC molecules.
- T cells can be divided into different subsets based on the expression of one or other T-cell receptor (TCR-1 or TCR-2).
**Fig. 3.4 Involvement of TH1 and TH2 cells in immunity.**

- **TH1 effects**
  - Reinforces early local responses
  - Promotes cell-mediated cytotoxic responses
  - Mediates type IV delayed type hypersensitivity

- **TH2 effects**
  - Activates later systemic responses
  - Promotes humoral antibody responses
  - Promotes allergic type 1 hypersensitivity responses
  - Limits inflammatory responses

**Fig. 3.5 T-cell receptor (TCR) complex.**
• TCR-1 cells are thought to have a restricted repertoire and to be mainly non-MHC restricted.
• TCR-2 cells express either CD4 or CD8 which determines whether they see antigen in association with MHC class II or I molecules.

**T-cell recognition of an antigen**
• T cells recognize antigens that originate within other cells, such as viral peptides from infected cells.
• T cells bind specifically to antigenic peptides presented on the surface of infected cells by molecules encoded by the MHC.
• The T cells use their specific receptors (TCRs) to recognize the unique combinations of MHC molecule plus antigenic peptide (Fig. 3.6).

The stages in the recognition and processing of a virally infected cell by a cytotoxic CD8+ T cell are:
1. Entry of virus into the target cell.
2. Replication of the virus.
3. Processing of viral proteins to generate antigenic determinants which associate with MHC (HLA) class I molecules.
4. Presentation of the antigen–HLA complex for recognition by a specific CD8 cytotoxic cell, with killing of the infected cell.
5. The naïve T cells that emerge from the thymus are pre-cytotoxic T lymphocytes, and require further activation and differentiation to become the effector T cells that lyse virally infected target cells and tumour cells.

**The \(\gamma\delta\) T-cell subset**
• \(\gamma\delta\) TCR-expressing T cells are a minor population (> 5%) of all T cells and are a separate lineage from the \(\alpha\beta\) T cell that differentiates into CD8+ and CD4+ cells.
• The γδ TCR recognizes antigen differently without processing or presentation on a MHC class I or class II molecule, e.g. non-peptide antigen such as bacterial cell wall phospholipids.
• They act as part of the first line of defence, recognizing pathogens mainly in the skin and gut.
• They can secrete cytokines, help B cells, activate macrophages and lyse virally infected cells.

2. GRANULOCYTES
• Neutrophils (PMNs): strongly phagocytic cells important in controlling bacterial infections.
• Eosinophils: weakly phagocytic: main role is in allergic reactions and destruction of parasites.
• Basophils and mast cells: non-phagocytic granulocytes that possess cell-surface receptors for IgE. Mediate allergic and antiparasitic response due to release of histamine and other mediators.

3. MACROPHAGES
Monocytes are released from the bone marrow, circulate in the blood and enter tissues, where they mature into macrophages.

Functions
1. Phagocytose microbes.
2. Secrete inflammatory mediators and complement components.
3. Present antigen associated with class II MHC and CD4+ cells.
4. Secrete numerous cytokines that promote immune responses (IL-1, TNF-α, IL-6 and IL-12).

Phagocytosis of microbes by neutrophils and macrophages
1. Bacteria are opsonized by IgM, IgG, C3b and C4b, promoting their adherence and uptake by phagocytes.
2. The killing activity of neutrophils and macrophages is enhanced by highly reactive compounds: oxygen-dependent (hydrogen peroxide $H_2O_2$, superoxide anion, hydroxyl radicals, hypochlorous acid and nitric oxide (NO)) and oxygen-independent (acids, lysozyme–degrades, bacterial peptidoglycan, defensins (damage membranes), lysosomal proteases, lactoferrin (chelates iron). Their formation by NADPH oxidase, NADH oxidase or myeloperoxidase is stimulated by a powerful oxidative burst following bacterial phagocytosis.

4. DENDRITIC CELLS
Found in various tissues, e.g. Langerhans cells of the skin, peripheral blood and lymph glands.

Functions
1. Antigen-presenting cells: efficient at presenting antigen to both CD4+ and CD8+ cells.
2. Have phagocytic activity and release cytokines.
**Antigen-presenting cells**
- Include macrophages, monocytes or their derivatives (microglial cells, Kupffer cells and skin Langerhans cells).
- Characterized by their ability to phagocytose, internalize and process antigen.
- Possess Ia antigen, Fc receptors and C3b receptors and produce interleukin 1.

5. NATURAL KILLER (NK) CELLS

**Functions**
1. Similar function to lymphocytes – kill virus-infected cells and some tumour cells, and produce cytokines.
2. Recognition of target differs from lymphocytes – they do not bind MHC, and a carbohydrate receptor selects target. NK cells express two major classes of inhibitory receptors for MHC molecules: lectin-like receptors of the CD94 family and immunoglobulin superfamily molecules (KIRs).
3. Act rapidly, and constitute an early antiviral defence.
4. Identified by: Fc receptor for IgG.
5. Previously referred to as large granular lymphocytes (IGL) because of their appearance.

*Mechanisms of NK cell killing*
- Direct cytotoxicity involving contact with target cell and lysis by perforin-mediated mechanism similar to that used by Tc cells, except it is antigen independent and non-MHC restricted.
- Antibody-dependent cellular (ADCC) cytotoxicity. Binding of Fc receptors on NK cells to antibody-coated target cells initiates killing. (Neutrophils, eosinophils and macrophages also exhibit ADCC).

6. CYTOKINES (Fig. 3.7)

- Small protein signalling molecules (usually glycoproteins) of relatively low molecular weight.
- They regulate important biological processes: proliferation and differentiation, growth inhibition, apoptosis, chemotaxis and chemokinesis, resistance to viral infection, induction of cytotoxic effector cells, induction of phagocytes, promotion of intercellular adhesions and regulation of adhesion to extracellular matrix.
- Many cytokines act by causing aggregation of receptors at the cell surface, which leads to activation of second messenger system.
- The main cytokines are interferons, interleukins, tumour necrosis factor, growth factors, colony stimulating factors and chemokines.

1. Interferons (IFNs) (Table 3.3)
   These glycoproteins are produced by virus-infected cells.
   - Three species of interferon:
     1. Alpha-interferon (IFN-α) produced by human leucocytes
     2. Beta-interferon (IFN-β) produced by human fibroblasts
   - Properties:
     1. Prevent viral replication
     2. Antitumour activity
     3. Activate macrophages and natural killer (NK) cells.
Fig. 3.7 Interrelationship of immune cell populations.

</tr>
</tbody>
</table>
2. Interleukins (ILs) (Table 3.4)
These cytokines stimulate proliferation of T helper and cytotoxic cells and B cells. Interleukin-1 (IL-1) is a central regulator of the inflammatory response.
- Synthesized by activated mononuclear phagocytes.
- IL-1β is secreted into the circulation and cleaved by interleukin-1β converting enzyme (ICE).
- IL-1β levels in the circulation are only detectable in the following situations: after strenuous exercise, in ovulating women, sepsis, acute organ rejection, acute exacerbation of rheumatoid arthritis.
- Acts in septic shock by increasing the number of small mediator molecules such as PAF (platelet-activating factor), prostaglandins and nitric oxide which are potent vasodilators.
- The uptake of oxidized low density lipoproteins (LDL) by vascular endothelial cells results in IL-1 expression which stimulates the production of platelet-derived growth factor. IL-1 is thus likely to play a role in the formation of the atherosclerotic plaque.
- IL-1 has some host defence properties, inducing T and B lymphocytes, and reduces mortality from bacterial and fungal infection in animal models.
Interleukin-2 (IL-2) is also known as T-cell growth factor.
- Induces proliferation of other T lymphocytes; generates new cytotoxic cells, and enhances natural killer cells.

3. Tumour necrosis factor (TNF) (Table 3.5)
- The principal mediator of the host response to Gram-negative bacteria. May also play a role in the response to other infectious organisms, and is a key cytokine in the pathogenesis of multiorgan failure.
- Activates inflammatory leucocytes to kill microbes; stimulates mononuclear phagocytes to produce cytokines; acts as a costimulator for T-cell activation and antibody production by B cells; and exerts an interferon-like effect against viruses.
4. Growth factors

**Transforming growth factor-beta (TGF-β)**
- Generally limits inflammatory response.
- Enhances IgA synthesis.
- Initiates and terminates tissue repair.
- Undergoes autoinduction.
- Released by platelets at the site of tissue injury and promotes the formation of extracellular matrix.
- Implicated in diseases of tissue fibrosis such as cirrhosis and glomerulosclerosis.

5. Colony stimulating factors (CSFs)

- These are involved in directing the division and differentiation of bone-marrow stem cells, and the precursors of blood leucocytes.

### Table 3.6 Colony stimulating factors (CSFs)

*Not a typical cytokine as it has a single origin.

6. Chemokines

- Large family of cytokines that have chemoattractant properties.
- Responsible for recruiting leucocytes to inflammatory lesions, inducing release of granules from granulocytes, regulating integrin avidity and in general exhibiting proinflammatory properties.
- Chemokines are secreted by many cell types.
- The receptors for the chemokines are also family-specific (Table 3.7).
Cytokine disorders
Both cytokine overexpression and underexpression or their receptors can be pathogenic:
1. Septic shock: production of IL-1, IL-6 and TNF due to endotoxin stimulation of macrophages following Gram-negative infection.
2. Toxic shock syndrome: massive release of cytokines due to superantigen stimulation of T-cells by TSST-1, a bacterial exotoxin.
3. Chagas’ disease (T. cruzi infection): causes reduced expression of IL-2 receptor, leading to marked immune suppression.

7. ACCESSORY MOLECULES
Promote adhesion of T cells and/or signal transduction leading to T-cell activation.

Adhesion molecules (Table 3.8)
- Involved in cell–cell communication and recognition (i.e. help bind T cells to antigen-presenting cells and target cells), and control leucocyte migration (i.e. help direct T cells to sites of inflammation and lymph nodes).
- They fall into families that are structurally related:
  - The cell adhesion molecules (CAMs) of the immunoglobulin superfamily (antigen presentation)
  - the cadherin superfamily (neuromuscular interaction)
  - integrins (interaction between cells and the extracellular matrix)
  - selectins (leucocyte adhesion to endothelium during inflammation).

</tbody>
</table>

LFA, lymphocyte function-associated antigen; VLA, very late antigen; ICAM, intercellular adhesion molecule; VCAM, vascular cell adhesion molecule.

Coreceptor activating molecules (e.g. CD28, CTLA-4)
- Transduce signals important in regulating functional responses of T cells.
8. OTHER MOLECULES

Heat shock proteins

The heat shock response is a highly conserved and phylogenetically ancient response to tissue stress that is mediated by activation of specific genes. This leads to the production of specific heat shock proteins that alter the phenotype of the cell and enhance its resistance to stress. Their principal function appears to be to act as molecular chaperones for damaged protein to direct it into degradation pathways such as ubiquitination.

Free radicals

- A free radical is literally any atom or molecule which contains one or more unpaired electrons, making it more reactive than the native species.
- Free radical species produced in the human body are:
  - OOH* (peroxide radical) – O2* (superoxide radical)
  - OH* (hydroxyl radical) – NO* (nitric oxide).
- The hydroxyl radical is by far the most reactive species, but the others can generate more reactive species as breakdown products.
- When a free radical reacts with a non-radical, a chain reaction ensues which results in the formation of further free radicals and direct tissue damage by lipid peroxidation of membranes (particularly implicated in atherosclerosis and ischaemic reperfusion injury within tissues).
- Free radical scavengers bind reactive oxygen species.
- Principal dietary antioxidants:
  - Vitamin E
  - β-Carotene
  - Vitamin C
  - Flavonoids.
- Patients with dominant familial forms of amyotrophic lateral sclerosis (motor neuron disease) have mutations in the gene for Cu–Zn SOD-1, suggesting a link between failure of free radical scavenging and neurodegeneration. Protection against heart disease and cancer may be conferred by dietary antioxidants.

Nitric oxide (NO)

NO is an important transcellular messenger molecule which is involved in a diverse range of processes.
- NO is synthesized from the oxidation of nitrogen atoms in the amino acid L-arginine by the action of NO synthase (NOS; Fig. 3.8).
- NO acts on target cells close to its site of synthesis, where it activates guanylate cyclase, leading to a rise in intracellular cGMP which acts as a second messenger to modulate a variety of cellular processes. It has a very short half-life.
- There are at least three distinct isoforms of NO synthase:
  1. Neuronal (constitutive) NO synthase (CNS neurotransmission, memory formation)
  2. Endothelial (constitutive) NO synthase (vasodilator tone modulation, organ-specific microcirculatory control, e.g. kidney)
  3. Macrophage (inducible) NO synthase.

![Fig. 3.8 Synthesis of nitric oxide.](image)
APOPTOSIS (see also p. 35)

- Is the process of programmed cell death, and is a mechanism for the elimination of excess or damaged cells.
- Several genes have been identified that either promote (bax, bak, bcl-Xs) or inhibit (bcl-2, bcl-XL, bcl-w) apoptosis. Antiapoptotic genes could confer characteristics such as longer survival.
- It is mainly triggered through the Fas–Fas ligand interaction. Binding of Fas ligand (expressed on a killer T cell) to Fas expressed on a target cell triggers a cascade of intracellular biochemical changes in the target cell. Fas interacts with several proteins in the ‘death pathway’ to activate a proteolytic enzyme, caspase. The caspase proteolytic cascade then activates a cytoplasmic enzyme (caspase-activatable DNAase (CAD)) which can then migrate to the nucleus and cleave DNA into small fragments, which are the end-point of apoptosis.
- It has several important roles in shaping the adaptive immune response, e.g. after an immune response to a pathogen, redundant lymphocytes are cleared by apoptosis.
- It is also involved in some pathological processes, e.g. destruction of CD4+ cells in HIV infection; can lead to the production of autoantibodies against DNA and result in autoimmune disease; clones of B cells that have increased levels of bcl-2 through mutations may be protected from apoptosis and develop into a B-cell malignancy.

IMMUNOGLOBULINS

PROPERTIES, FUNCTIONS AND REACTIONS

The properties and functions of the major classes of immunoglobulins are shown in Table 3.9, and the immunological reactions of IgG, IgA and IgM are summarized in Table 3.10.
<table>
<thead>
<tr>
<th>Ig class</th>
<th>Heavy chains</th>
<th>Molecular weight</th>
<th>% total Ig level</th>
<th>Normal plasma level</th>
<th>Function</th>
</tr>
</thead>
</table>
| IgG      | γ            | 150 000 (monomer) | 80              | 8–16 g/l            | 1. Distributed in blood and interstitial fluids  
2. The major immunoglobulin of the secondary immune response*  
3. The only immunoglobulin that crosses the placenta, and therefore the major protective immunoglobulin in the neonate. Most maternally transmitted IgG has disappeared by 6 months†  
4. Opsonization, toxin neutralization and agglutination. Coats cells prior to killing by killer cells. Activates complement via classical pathway |
| IgA      | α            | 160 000 (dimer and secretory form) | 13              | 1.4–4 g/l          | 1. Principal immunoglobulin in secretions of respiratory and gastrointestinal tract and in sweat, saliva, tears and colostrum. Key defence role for mucosal surfaces  
2. Polymerizes to a dimer intracellularly by binding through a cysteine-rich polypeptide (J-chain), synthesized locally by submucosal cells  
3. Secreted through epithelia as the dimer bound to a secretory transport piece, synthesized locally by epithelial cells  
4. When aggregated binds polymorphs and activates complement by the alternative pathway |
| IgM      | μ            | 900 000 (pentamer) | 6               | 0.5–2 g/l          | 1. Macroglobulin made up of five monomeric immunoglobulin subunits linked by a J-chain  
2. Mainly intravascular  
3. Principal immunoglobulin of the primary immune response  
4. Does not cross the placenta. Fetal production of high levels of specific IgM in intrauterine infection may be of diagnostic significance, e.g. rubella  
5. Agglutinates and opsonizes particulate antigens. Activates complement via the classical pathway. Blood group antibodies: IgM |

* Secondary antibody response characterized by: 1. lowering of the threshold of immunogen; 2. shortening of the lag phase; 3. a higher rate of antibody production; 4. longer persistence of antibody production.

†Transient disease in the newborn caused by maternal IgG: rhesus incompatibility, autoimmune thrombocytopenia, thyrotoxicosis, myasthenia gravis, lupus erythematosus.
<table>

</thead>
</table>
| IgD      | δ            | 170 000 (monomer)| 0.1             | 4–40 mg/l           | 1. Precise functions are unknown  
2. Nearly all immunoglobulin is present as cell surface receptor on human B cells and may be involved in B-cell activation |
| IgE      | ε            | 185 000          | 0.002           | 0.1–1.3 mg/l        | 1. Immediate hypersensitivity reactions: binds to mast cells and basophils via its Fc fragment, which degranulates and releases biologically active mediators, e.g. histamine, when exposed to the appropriate antigen. Possibly of benefit in controlling certain parasitic infections  
2. Serum levels correlate with severity of asthma  
3. Activates various cells involved in allergic and inflammatory disease, which are activated by 2 main types of cell surface receptor: the FESR1 receptor on mast cells, basophils and eosinophils, and the FqSR2 receptor on lymphocytes. Receptor blocking monoclonal antibodies have been developed as possible asthma therapies |
STRUCTURE OF IMMUNOGLOBULIN MOLECULE (Fig. 3.9)

- An immunoglobulin molecule is a 4-polypeptide chain structure with two heavy and two light chains linked covalently by disulphide bonds.
- Treatment of the antibody unit with papain produces:
  - Two identical univalent antigen-binding fragments (Fab), each containing one antigen-binding site, and
  - One crystallizable fragment (Fc), which contains sites for complement fixation, reactivity with rheumatoid factors, skin and macrophage fixation and regulation of catabolism.

- **Light chains**
  - Molecular weight of approximately 23 000.
  - Two types: kappa (κ) and lambda (λ). Each immunoglobulin molecule has either two κ or two λ chains.

- **Heavy chains**
  - Molecular weight of about twice that of light chains (i.e. 50 000–75 000) and twice the number of amino acids.
  - Five classes of immunoglobulin are recognized on the basis of the Fc fragment of the heavy chain, i.e. heavy chain isotypes IgG, IgA, IgM, IgD and IgE. Heavy chain classes are also divided into subclasses of molecules, e.g. IgG1, IgG2, etc.

**Table 3.10** Summary of reactions of various immunoglobulins

**Fig. 3.9** Structure of the immunoglobulin molecule.

Fc = crystallizable fragment, Fab = antigen-binding fragment.
Both heavy and light chains consist of two regions (Table 3.11):
1. A constant region ($C_h$ and $C_l$), in which the amino acid sequence of immunoglobulins of the same class is more or less identical.
2. A variable region ($V_h$ and $V_l$) where the amino acid sequence varies considerably from molecule to molecule and contributes to the antigen-binding site.

Table 3.11 Antigenic determinants on antibodies

<table>
<thead>
<tr>
<th>Epitope class</th>
<th>Location</th>
<th>Comment on epitope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Isotype</td>
<td>Constant region</td>
<td>5 human isotopes are IgA, IgD, IgE, IgG, IgM. Each class of Ig heavy chains are identical in all members of a species</td>
</tr>
<tr>
<td>Allotype</td>
<td>Constant region</td>
<td>Vary among individuals of the same species. IgG exhibits the most allotypic difference</td>
</tr>
<tr>
<td>Idiotype</td>
<td>Variable region</td>
<td>Differ among antibodies with different antigen-binding specificities. Monoclonal antibodies have the same idiotype. Anti-idiotypic antibodies will resemble the original antigenic determinant group</td>
</tr>
</tbody>
</table>

Development and activation of B cells
- Direct B cell/T, cell interaction and cytokines secreted by T, cells are required for B cells to respond to most antigens.
- Stimulation of B cells by protein antigens induces generation of memory B cells and antibody-secreting plasma cells.
- During this clonal expansion and differentiation, the antibody affinity for antigen may change (affinity maturation), and the biological activities of the antibody can change (isotype class switching).

CLINICAL CONSIDERATIONS (see Table 3.12)

Table 3.12 Immunoglobulin products for replacement therapy

<table>

PARAPROTEIN
- A homogeneous band of one immunoglobulin, usually IgG, IgM or IgA. Its presence implies proliferation of a single clone of cells.
